Abstract 4928

BACKGROUND

- The PI3K, AKT, and mTOR (PAM) pathway (**Figure 1**) is one of the most commonly activated oncogenic pathways in gynecological cancers, such as endometrial cancer (EC), ovarian cancer (OC), and cervical cancer (CC) (**Table 1**). Loss of PTEN function and PIK3CA activating mutations are especially frequent in EC (**Table 1**).
- Targeting the PAM pathway, in combination with other cooperative oncogenic pathways (e.g., the estrogen pathway), is a promising strategy for cancer treatment, including gynecological cancers²⁻⁴. Currently, the combination of everolimus, an mTORC1 inhibitor, and letrozole, an aromatase inhibitor, is an NCCN recommended regimen for patients with recurrent or metastatic endometrioid EC⁵.
- Most PAM inhibitors (PAMI) selectively spare or weakly inhibit one or more key PAM pathway components, which can lead to drug resistance⁶. To minimize drug resistance, a more comprehensive inhibition of the PI3K isoforms and downstream mTOR complexes may be required.
- We hypothesized that gedatolisib, which potentially inhibits all Class I PI3K isoforms, mTORC1, and mTORC2, can more effectively inhibit proliferation of EC and other gynecological cancer cells than other PAM inhibitors targeting individual PAM pathway components.

METHODS

Cell Lines. A panel of 26 well-characterized EC, OC, and CC cell lines were used in this study (**Table 2**). Cells were maintained according to ATCC recommendations and authenticated by STR profiling. Genetic alterations in PAM pathway genes were identified by cBioPortal (<https://www.cbioportal.org/>) analysis of the Cancer Cell Line Encyclopedia (CCLE)⁸.

Treatments with PAM Inhibitors. Cells were seeded on 24- or 96-well plates coated with collagen-fibronectin-laminin, let attach overnight, and treated with PAM inhibitors (**Table 3**) at increasing concentrations to obtain dose response curves (DRCs). The seeding density of each cell line was optimized to ensure untreated cells remained in the growth phase throughout the assay.

Viability and proliferation-normalized inhibition of growth rate (GR) assays. After 72h PAMI treatment, cell viability was measured by RT-Glo MT assay (Promega) using a luminescence microplate reader. The normalized growth rate inhibition (GR) and per-division drug potency (GR50) metrics were calculated using the online GR calculator tool (<http://www.grcalculator.org/grcalculator/>) and the cell division time for each cell line. The normalized GR inhibition approach was used to rule out confounding effects of traditional IC50 metrics, such as the number of cell divisions occurring during the assay^{7,9} (<http://www.lincoproject.org>).

FACS analysis. After 48h PAMI treatment, cells were harvested from 24-well plates, stained with a fixable viability dye (Zombie), fixed in 1.6% PFA, permeabilized with methanol, stained with antibodies, and analyzed by flow cytometry on the Agilent Novocyte 3005. To quantify cell proliferation, cells were cultured in the presence of 10 μ M EdU for 2 hr prior to analysis by FACS using Click-It chemistry (Invitrogen). Antibodies against pRPS6 and p4EBP1, two markers that integrate PAM signaling pathway outputs from PI3K/mTORC1 and mTORC2/pAKT (**Figure 1**), were used to assess PAM pathway inhibition by the PAMI¹⁰.

Xenografts. Immunodeficient female mice (nu/nu, SCID, or NOD.SCID) were inoculated subcutaneously in the flank with tumor pieces derived from MFE-280, MFE-296, AN3CA, or RL95-2 cell lines. When tumor size reached ~100–250 mm³, mice (N = 6–10 per arm) were randomly assigned to either a control vehicle group or a treatment group that received gedatolisib as indicated. Mice were treated every 4th day or twice a week for 12–21 days depending on the xenograft model.

Figure 2. Cell Viability Analysis of EC, OC, and CC Cell Lines Treated With Gedatolisib and Other PAM Inhibitors

The RT-Glo MT assay was used to obtain cell viability DRCs in a panel of 24 EC, OC, and CC cell lines treated for 72 hours with various PAM inhibitors at increasing concentrations:

- 1.4–3000 nM for gedatolisib, copanlisib, and everolimus
- 12–27000 nM for alpelisib and capivasertib

(A) Dose response curve (DRC) for the AN3CA EC cell line. Data are relative to DMSO-treated cells (set as 1) and represent mean $\pm$ SD. (B) Heatmap summarizing the DRCs of all the cell lines tested. (C) Summary tables of potency (left) and efficacy (right) based on IC50 values and viability % inhibition for the various PAM inhibitors. The % inhibition values shown in B and C are relative to DMSO-treated cells.

- The pan-PI3K/mTOR inhibitor, gedatolisib, exhibited superior potency and efficacy in most of the cell lines tested relative to the other inhibitors evaluated, regardless of the PAM pathway mutational status.
- Gedatolisib showed similar potency and efficacy in cell lines with wild type or altered PAM pathway genes.

Figure 3. Normalized Growth Rate Inhibition (GR) Metrics Were Used to Characterize Cytostatic and Cytotoxic Effects of PAM Inhibitors

GR metrics were used to rule out confounding effects of individual cell line proliferation rates on drug responses. (A) The normalized GR inhibition approach allows to identify both cytostatic and cytotoxic drug effects. GR values below zero reveal cytotoxicity of drugs not evident from the IC50 metric. (B) Example of GR value DRCs in response to PAMI in the AN3CA EC cell line. (C) GR-based metrics showing GR50 (potency) and GR values (efficacy) for gedatolisib and other PAMI in the panel of EC, OC, CC cell lines.

- The pan-PI3K/mTOR inhibitor, gedatolisib, exerted potent anti-proliferative and cytotoxic effects, regardless of PTEN or PI3K status
- On average, the cytostatic and cytotoxic effects of gedatolisib were superior to the other PAM inhibitors evaluated.

RESULTS

Figure 4. Assessment of DNA Replication and PAM Signaling Markers in EC Cell Lines

A panel of five EC cell lines was treated for 48 hours with escalating doses of PAM inhibitors and analyzed by flow cytometry for markers of DNA replication (EdU incorporation) and PAM signaling activity (pRPS6 and p4EBP1). (A) Examples of PAMI DRCs in AN3CA cells. Data are relative to DMSO-treated cells (set as 1) and represent mean $\pm$ SD. (B) Heatmaps summarizing PAMI DRCs (1.4–1000 nM for gedatolisib, copanlisib, and everolimus; 12
